A Lagos home that swaps its generator for solar stops about 2 tonnes of CO_2 a year. KlimateX proves it, sells it, and pays the family through Access Bank.

The inverter measures what solar replaced. Software checks it, an auditor confirms it, each tonne becomes a serial-numbered credit, a company retires it, and the family is paid through Access.

THE IDEA IN ONE LINE

Small climate wins earn nothing because proving them costs more than they earn. Make the proof nearly free, and the money reaches the family.

$14bn	2.1 t	5.8 Mt	₦0
spent every year running generators in Nigeria[1]	CO_2 credited a year per home, after grid hours and cautious deductions[6,10]	credits issued to 57 Nigerian projects, almost none from homes[5]	what a family earns today for the fuel it stops burning[1]

1 The problem: the value is real, nobody measures it, so nobody pays

Nobody records it
No one logs the kWh solar delivers or the fuel it replaces.

One home is too small to audit
Auditing one home costs more than its 2 credits a year earn.

Generators move, they don't die
A resold generator keeps burning in someone else's shop.

The upfront cost stops most homes
Tunde Mosanya was quoted ₦3m for 4 kW and kept his generator.[3]

The result: Catherine Ime ran a generator for six years, then paid for solar herself.[1] The carbon she avoids earns her nothing. KlimateX helps the next family afford the switch.

2 Why now

JAN 2026
National Carbon Market Framework: a registry and MRV rules.[4]

MAR 2026
Gold Standard's first method for replacing generators with renewables.[6]

JUN 2026
Africa's #2 solar market; 3,940 MW of grid for 220M+ people.[1]

NOV 2026
The Forge sandbox ships a carbon registry API.[9]

3 The solution: grade, measure, verify, pay

GRADE
Every home gets A to G
From its metered generator share, with an Access loan to go up.

MEASURE · CORE
Read the inverter
Gold Standard's generator equations, run on metered kWh.[6]

VERIFY
Nine checks, one score
Sunlight, clones, spikes, scrapped generator. Then an auditor samples.

PAY
Sold once, traced to the naira
Buyer pays, credits retire, the ledger splits, the family is paid.

The audit-cost problem, answered: thousands of homes on one data pipeline are one project. Software does the checking; the auditor samples it. When in doubt, we credit less.

4 The demo: six months in 20 Surulere homes, a fraud caught live, 10 credits sold

On the Access sandbox

Readings in	Fraud caught	18 credits	Buyer retires 10	Families paid
20 inverters, Jan to Jun 2026.	Home 17 beats the sun. Home 19 copies Home 4. Held.	17 homes, 18.0 t, auditor signs off.	Pays ₦150,000; certificate with QR.[10]	₦75,000 split across 17 wallets.

PILOT TARGETS **200 Lagos homes**, ~210 t audit-ready in 6 months **0 tonnes** issued without sign-off

Every naira traced to a home

Why KlimateX pays, and who it pays

The carbon credit is how we prove a home's saving. The bigger prize is what that proof unlocks for Access Bank: solar loans priced on metered savings, new customers, and deposits from every naira that flows through the platform.

1 Who is involved, and what each gains

PARTY	WHAT THEY GAIN
Families	Carbon payouts, lower fuel bills, a solar loan priced on real savings, a grade that shows what to do next, a quieter home.
Access Bank	New customers, deposits, fee income, and safer solar lending backed by metered data.
Installers	A 15% share of carbon income, more sales from the grade and loan offer, accredited status, a fleet dashboard.
Credit buyers	Credits tied to a real home and month, publicly checkable and retired in their name, with a Nigerian story.
Auditors, registries	Household projects that were too costly to verify before, with clean data in the methodology's own fields.[6]
Government	Verified progress on climate targets, authorisation fees on exported credits,[12] a live view of the move off generators.
Recyclers	A steady supply of scrapped generators, paid for issuing proof of destruction.

2 How the money moves

1 · PAY
Buyer pays ₦150,000
for 10 credits at checkout

2 · HOLD
Access holding wallet
until payment is confirmed

3 · RETIRE
In the buyer's name
can never be sold again

4 · SPLIT
Ledger pays out
by tonnes each home earned

50% Families	15% Installer	20% Audit, registry	15% KlimateX
₦75,000	**₦22,500**	**₦30,000**	**₦22,500**

Families are paid after each audit. Government fees, if credits are authorised for export, come off before the split.[12] Price ₦15,000 a credit and the split are illustrative.[10]

Who pays to scrap the generator?

Trade it in. Its scrap value becomes the deposit on the Access solar loan. For larger estates, a buyer pre-pays for future credits and that money funds the switch.

What Access Bank gains

Deposits in wallets, every family and installer as a customer, and a solar loan book priced by grade, with carbon payouts going straight to repayments.

3 Model & roadmap

- **Green lending:** a fee on every solar loan priced on our data. The main line.
- **Marketplace:** 15% of every credit sold.
- **Certificates and data:** installer dashboards, grid maps, lender reports.

Nov '26	Forge build on the sandbox
H1 '27	Lagos pilot: 200 homes metered
H2 '27	Gold Standard registration, NCCC authorisation
2028	Shops, towers, Ghana and Kenya

4 Our ask

- Production access to Access wallet, escrow and payout APIs
- An intro to Access's solar and SME lending team, to price a pilot loan by grade
- 1–2 installers from Access's SME book whose inverters already report data
- Access as first buyer of the pilot's credits

Sources on page 11.

How KlimateX works

KlimateX reads a home's inverter, runs Gold Standard's own generator equations on it, checks it nine ways, and only then lets an auditor turn it into credits.[6]

METHOD
Gold Standard JUST: Fossil Fuel Generators v1.0

SCENARIO
Weak grid (B): solar split between generator and grid

UNIT AN AUDITOR SIGNS
A 6–12 month monitoring period

DATA THE ENGINE SEES
kWh, serials, location. No BVN.

1 A home's path through KlimateX

1 · JOIN
Consent signed. Old generator traded in and scrapped, recycler proof on file.

2 · READ
Daily kWh from the inverter, tied to one serial and one address.

3 · COUNT
Tonnes avoided per home per month, using the method's equations.

4 · CHECK
Nine checks give a trust score; only 80+ can earn credits.

5 · AUDIT
Auditor samples homes, signs the period, credits are issued.

6 · PAID
Buyer retires credits; the family's share is paid.

2 The carbon maths, one home, one month

Tonnes avoided = solar kWh × (generator share × generator factor + grid share × grid factor), less a net-zero adjustment, project and leakage emissions.[6]

Solar credited is capped at what the old generator could have produced. Homes where solar delivers less than the generator did get a leakage penalty.

Solar to the home	152 kWh
Grid 6 h a day, so shares	75% gen · 25% grid
0.152 × (0.75 × 1.59 + 0.25 × 0.40)	0.197 t
Less 5% net-zero adjustment, project emissions	**≈ 0.18 t**

About 2.1 t a year. Our first estimate was 2.9 t; it ignored grid hours. Factors 1.59 and 0.40 t/MWh and the 5% are placeholders until confirmed from the method's annexes.[8,10]

3 Nine checks before a tonne counts

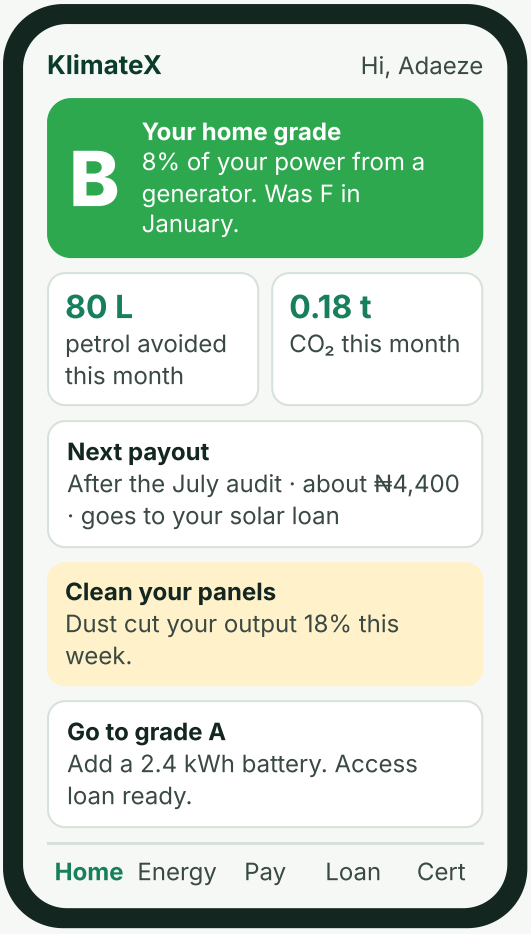

CHECK	RULE	IF IT FAILS
Sunlight	Daily kWh ≤ NASA sunlight × panel size × 1.1	That day fails
Energy balance	Power used ≤ power made + battery	Flag
Clone	Profile matches another inverter over 14 days	Both held
Flat line	No natural variation over 7 days	Flag
Spike	A day over 3× the 30-day median	That day fails
Missing data	No reading for a day	Counts as zero
Identity	Serials unique; install photo within 200 m	Home blocked
Scrapped	Scrap photo, recycler certificate, date	Tonnes held
Backup share	Backup generator ≤ 10% of output	Ineligible that year

Trust score 0–100: 80+ earns credits; 50–79 is held and always in the auditor's sample; under 50 is excluded and the family is told why.

Sources on page 11.

What we are building: two phone apps, four dashboards, one public page

Every screen runs on the same backend and data. Phone apps are installable web apps for the demo, built mobile-first; native apps and WhatsApp come in the pilot. Tags show what is ready for the Stage 2 demo on Wednesday, for Demo Day, or for the pilot.

Household app (phone)

Wed

For families. Plain words, naira and litres, never jargon.

Home	Grade, litres and CO_2 this month, next payout, alerts
Energy	Daily solar against the sunlight ceiling; grid hours; backup share
Payouts	Each audit period: tonnes, naira, where the money went
Loan	Balance, repayments made by carbon payouts, upgrade offer
Certificate	Home Energy Certificate to view, share or download
Alerts	Dust on panels, inverter offline, backup use nearing 10%

Installer app (phone)

Wed · fleet view Demo Day

For accredited installers in the field. Onboards a home in one visit.

Onboard	Family e-signs consent; site location; grid hours
Generator	Nameplate and serial photos; trade-in value; scrap certificate upload
Inverter	Pair the serial; GPS-tagged install photo; first reading confirmed
Fleet	Every home installed, trust scores, alerts, the installer's earnings

1 The four dashboards and the public page

Auditor portal

Wed

Monitoring periods, a sample drawn with a visible seed, each home's evidence (checks, charts, photos). Mark sites reviewed, sign off, and serials are minted.

Buyer marketplace

Wed

Browse batches by vintage, area and authorisation. Reserve tonnes for 15 minutes, pay at Access checkout, retire, download the certificate with QR.

Access lender dashboard

Demo Day

Homes and loans by grade, repayments made by payouts, deposits held, at-risk homes (failing battery, offline), and the grid supply map.

Operations console

Wed, basic

Flag queue, split settings, payouts reconciled against bank webhooks: "pending" until the bank confirms, never "paid" early.

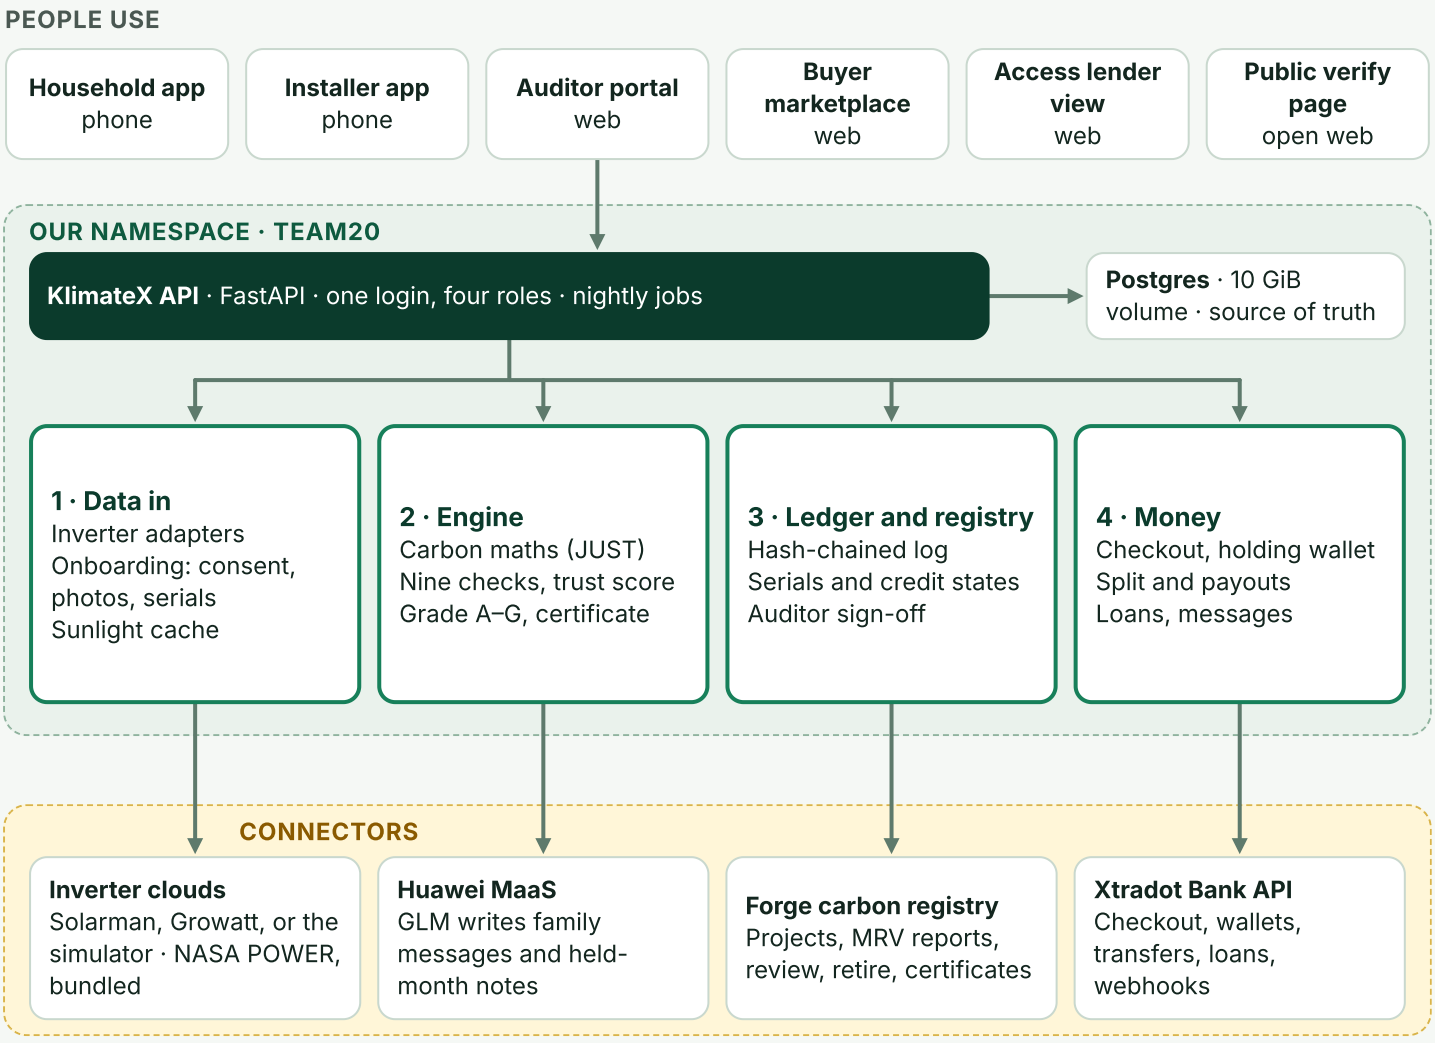

Public verify page (open to anyone)

Wed

Look up a credit serial or a home certificate number: vintage, area, home-months behind it (pseudonymised), checks, auditor sign-off, who retired it. The day's ledger hash is published here.

How it fits together: architecture and connectors

One backend, four modules, one database, the apps on top. Data flows one way only. The bank, registry and AI connectors sit behind the sandbox's internal gateway, reached with our team key.[9]

1 Every connector, and what it does

CONNECTOR	WHAT WE USE IT FOR	HOW WE CONNECT	IN THE DEMO
Xtradot Bank API	Checkout, wallets, transfers, loans, webhooks	Team key, idempotency keys, signed webhooks	Real (sandbox)
Forge carbon registry	Project, MRV, review, retire, certificates	Team key, internal gateway	Real (sandbox)
Huawei MaaS (GLM)	Family messages and held-month notes	Team key; never decides a credit	Real (sandbox)
Inverter clouds	Daily kWh per inverter	One adapter per vendor	Simulator
NASA POWER	Daily sunlight for the sunlight check	Public data, cached in our image	Bundled
WhatsApp, SMS	Monthly messages to families	Messaging provider [to choose]	Mocked
Gold Standard registry	Real issuance after the pilot audit	Export in the method's fields	Pilot

The chain that never breaks: home → inverter → reading → period → credit → retirement → payout. The database enforces unique serials, no credit without sign-off, an insert-only ledger, and money in kobo.

Sources on page 11.

The build, and the three-minute demo

One backend, one database, one web app with four views: household, installer, auditor and buyer. It runs in our team namespace on the Forge sandbox, because the bank and carbon registry APIs only answer from inside the cluster.[9]

1 Each part, mapped to the sandbox

PART	WHAT IT DOES	SANDBOX CALLS[9]
Ingest	20 synthetic homes, two planted frauds, NASA sunlight bundled in.	Our FastAPI service and Postgres
Engine	JUST equations and the nine checks, with evidence saved.	Runs in our pod
Registry	Project once; each period filed, reviewed, verified.	`/carbon/projects` · `/mrv` · `/review`
Checkout	Buyer pays; we verify, then retire the serials.	`/payments/checkout` · `/verify` · `/credits/retire`
Hold, split	Funds in a holding wallet; ledger splits on retirement.	`/wallets` · webhook `carbon.credits.retired`
Payouts	Name enquiry, then transfer with an idempotency key.	`/transfers/interbank` · `/wallets/transfer`
Loans	Solar loan priced by grade; payouts repay it.	`/loans/applications` · `/repayments`

Tamper-evident ledger

Every state change is written to an append-only log, each entry hashed with the one before. Change one past event and every later hash breaks. The latest hash is published daily. No tokens, so no double-counting questions.

Public verify page

Enter a serial and see its vintage, the home-months behind it (pseudonymised), the checks, the auditor's sign-off and who retired it. The buyer's certificate links here by QR code.

2 The demo, minute by minute

TIME	ON SCREEN	THE JUDGE LEARNS
0:00	Adaeze's certificate: grade F to B, generator scrapped, loan offer	A real activity, graded
0:25	Daily solar against the sunlight ceiling; tonnes, equations one click away	Metered, Gold Standard maths
0:50	Home 17 fails the sunlight check; Home 19 caught copying Home 4	Fraud caught by the system
1:20	Auditor draws a sample with a visible seed, signs off, 18 serials minted	Independent, one serial a tonne
1:50	Buyer pays ₦150,000 on the sandbox, 10 credits retired, certificate opens	Sold once, publicly checkable
2:30	Split runs; 17 family wallets rise; one goes straight to a loan	Every naira traced, through Access

Real vs simulated, said on stage

Real: the maths, all nine checks, NASA sunlight, the ledger, the sandbox wallets, payouts and registry calls.
Simulated: inverter data, households and installers, the auditor (a teammate), Gold Standard issuance.

Build plan

Mon: data, engine, checks, app live. **Tue:** registry, checkout, split, payouts; one credit through end to end by evening. **Wed:** code freeze 09:00, two clean rehearsals, backup video.

Sources on page 11.

WHAT IT REALLY DOES, IN 10 SECONDS

KlimateX grades a home's energy, helps it swap its generator for solar, proves the fuel saved, and pays the family through Access Bank.

IN 30 SECONDS

A home that swaps its petrol generator for solar stops about 2 tonnes of CO_2 a year. Companies pay for proven tonnes, but proving one home costs more than it earns. KlimateX reads the saving off the inverter, checks it against the sun, and files thousands of homes as one project, so the money can reach the family. Access Bank holds it, pays it out, and lends on the proof.

1 Six months, with and without KlimateX

Synthetic demo case, sandbox test data

A **Adaeze, Surulere.** Grade F: her generator supplied three quarters of her power.

S **Arewa Solar Co-op.** Quoted her for solar. She could not find the deposit.

B **Mama Nkechi Provisions.** A Lagos company that wants local credits it can defend.

WHEN	TODAY	WITH KLIMATEX
Jan · switch	No deposit, so the generator keeps running.	She trades in the generator as her deposit and takes an Access solar loan. It is scrapped.
Jan–Jun	Even if she switches, no one records the saving.	Her inverter reports daily. About 0.18 t a month, checked against Surulere's sunlight.
Jul · audit	Nothing to audit.	Her 1.06 t joins 16 other homes. The auditor signs; 18 credits are issued.
Jul · sold	Mama Nkechi buys credits from abroad.	She pays ₦150,000 and retires 10 Surulere serials.
Jul · paid	Adaeze earns nothing.	About ₦4,400 for her share so far, straight off her loan. More as the other 8 credits sell. Her grade is now B.

2 The numbers, checked by hand

₦15,000 a credit assumed[10]

CLAIM	WORKING	RESULT	WHAT IT TELLS US
Home, a month	0.152 MWh × 1.29 t/MWh, less 5% and project emissions	**0.18 t**	Page 3 shows the steps.
Home, a year	0.177 t × 12	**2.1 t**	28% below our first 2.9 t.
The demo	17 homes × 6 months × 0.177 t	**18 credits**	Whole tonnes only; fractions carry.
The pilot	200 homes × 2.1 t × 6/12	**210 t**	Audit-ready in six months.
A family	2.1 t × ₦15,000 × 50%	**₦15,750**	A year, paid after audits.
10,000 homes	21,000 credits × $10 × 15%	**$31,500**	A year from fees alone.

Read it as: the marketplace fee and the family's payout are both small. The value is the proof: a metered saving lets a bank lend for solar with less risk. That is why lending leads our model.

3 What it is worth to Access, assumptions shown

LINE	HOW IT IS COUNTED, AND WHO SUPPLIES THE NUMBER
Loan book	Solar loans written × (default rate today − default rate with metered savings). Both rates are Access's.
Deposits	Payouts held in wallets plus buyer funds awaiting retirement. Average balance is Access's number.
New accounts	Homes plus installers onboarded. Pilot: 200 homes, 1–2 installers.
Fees	Checkout, payout and loan fees at Access's tariff.

Sources on page 11.

Every home gets a grade, from A to G

In the UK, every home that is sold or let carries an Energy Performance Certificate: a grade, a score, the CO_2 the home produces, and a costed list of improvements. Banks price green mortgages on it and landlords need at least an E to let. Nigeria has nothing like it for homes. KlimateX can issue one, built from the same meter data that earns the carbon credits.

THE DIFFERENCE IN ONE LINE

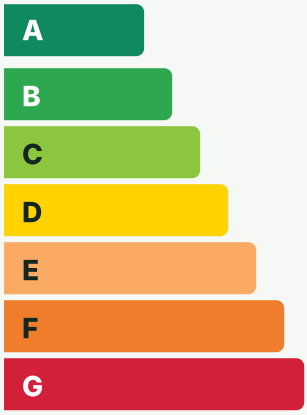

The UK certificate estimates. Ours measures.

A UK sample we read marks its walls, roof and floor as "assumed". Every line on ours says whether it was metered or assumed.

1 What we take from the UK certificate, and what we change

PART	UK ENERGY PERFORMANCE CERTIFICATE	KLIMATEX HOME ENERGY CERTIFICATE
How it is made	An assessor visits once and fills in a standard model. Parts the assessor cannot see are assumed from the home's age and type.	The inverter reports every day. Solar, grid and any backup generator use are metered.
The grade	A to G, from a modelled score out of 100.	A to G, from the share of the home's power that still comes from a generator.
Current and potential	Today's grade, and the grade after the suggested steps.	The same, with each step costed in naira and offered as an Access solar loan.
Valid for	10 years.	12 months, re-graded every month from meter data.
Who stands behind it	A named assessor, an accreditation scheme, a "no related party" declaration and a complaints route.	An accredited installer who declares no relationship to the household, plus a published dispute route.
Who uses it	Buyers, tenants, landlords, mortgage lenders.	Families, Access Bank's lending team, carbon buyers, and later landlords and insurers.

2 The KlimateX scale (proposed)

One number a family can check against its own bill. The bands are our design, to be tested in the pilot; this is not an official rating.

3 Why it strengthens KlimateX

The potential grade is a loan offer
"This home is F. With solar it could be B." The step is costed, the saving is shown, and the Access solar loan sits on the same page.

Access can price loans by grade
As UK lenders do with green mortgages. A metered grade is harder to game than a one-day survey.

It answers "is this additional?"
Homes still on generators get graded first, so KlimateX funds new switches, not only past ones.

It travels
The first metered home energy certificate for emerging markets. Carbon credits become one use of it.

In the demo: the household view opens on the certificate. It is built from data the build already holds (grade, CO_2, litres, payouts, the loan offer), so it adds one screen, not a new system. A sample for Adaeze's home is on the next page.

SAMPLE · synthetic household from the Forge sandbox test data · KlimateX scale (proposed), not an official rating

Home Energy Certificate

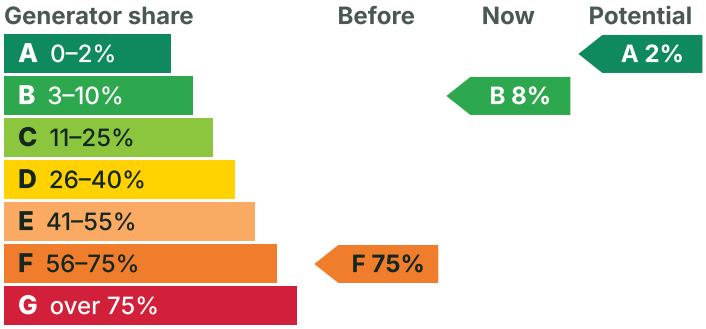

KlimateX · metered, not modelled

Home #0412
3-bedroom flat · Surulere, Lagos
Household: Adaeze (wallet wal_adaeze_01)

Grade **B**

Certificate	**KX-HEC-2026-LAG-000412**
Valid until	**8 Nov 2027 · re-graded monthly**
Measured	**Jan–Oct 2026, annualised**

Grade: before, now and potential

The grade is the share of the home's power that still comes from a generator. Before solar, the old generator supplied about three quarters of it.

Where this home's power comes from

Source	kWh a year	Share	How we know
Solar (to the home)	1,712	70%	metered
Grid	538	22%	metered
Backup generator, 1 kVA	196	8%	metered
Total use	**2,446**	**100%**	about 6.7 kWh a day

Old 3.5 kVA petrol generator: **scrapped 14 Jan 2026**, photo and recycler certificate on file. Backup use stays under the 10% limit.

Impact on the environment

Before solar	**3.2 t CO_2 a year**
This home now	**0.5 t CO_2 a year**
Credited to this home (after cautious deductions)	**2.1 t CO_2e a year**
Petrol no longer burned	**about 1,150 litres a year**

Generator factor 1.59 t/MWh, grid 0.40 t/MWh
assumed: published defaults, to confirm

What it earns and saves

Carbon payout, family's 50% share	**about ₦15,750 a year**
Paid	after each audit, to wal_adaeze_01
Fuel money saved	1,150 L × [pump price]

Payout uses an illustrative ₦15,000 a credit assumed

Steps to reach grade A

Step	Typical cost	Typical yearly effect
1. Add a 2.4 kWh battery	[installer quote]	Backup generator falls from 8% to about 2%: about 100 L less petrol and grade A
2. Swap remaining bulbs and fans to LED and DC	[installer quote]	Lower daily use, so the battery covers longer outages

Help paying: Access Bank solar loan, priced on this home's metered savings [rate set by Access] · carbon payouts can go straight to repayments.

Who stands behind this certificate

Installer	Arewa Solar Co-operative Society
Installer ID	[KlimateX accreditation ID]
Declaration	No related party
Disputes	[KlimateX support contact]

About this measurement

Inverter	Serial on file, one home only
Checks passed	Sunlight, identity, clone, flat line, backup share
Missing days	Counted as zero, never filled upward
Verify	Look up KX-HEC-2026-LAG-000412 on the public verify page

Beyond carbon: every meter reading does four jobs

The same inverter data that earns a credit can price a loan, map the grid and warn of a failing battery. That turns KlimateX from a carbon marketplace into energy data infrastructure, with Access as the bank on top.

FOUR JOBS, ONE READING

Prove carbon · price a loan · map the grid · warn before failure

1 Features for families and installers

Messages in their own language

A monthly WhatsApp or SMS: grade, litres saved, payout status. Written by Huawei GLM in Yoruba, Igbo, Hausa or Pidgin.[9]

Harmattan dust alert

When output falls below what the sun allowed: "Dust cut your output 18%, clean your panels." Keeps homes earning.

Solar sizing calculator

Enter monthly fuel spend; get system size, cost, loan repayment, payback and the grade you would reach.

Warning before failure

Battery and panel decline spotted in output patterns. Installers sell maintenance; Access sees loan risk early.

Street and estate grades

Homes rolled up into one grade per street or estate, for landlords, estates and local government.

Photo and satellite checks

Generator serials read from photos, reused scrap photos caught, panels confirmed from satellite images.

2 Features for Access Bank

Generator trade-in

Scrap value becomes the loan deposit. Fixes who pays for the buyback.

Energy-based credit score

A year of metered use and on-time repayments builds a record for people with none.

Insurance on real data

Theft and breakdown cover priced on how each system performs.

3 The grid map nobody has

Inverters record when grid power arrives. Across thousands of homes that becomes actual supply hours, street by street, useful to electricity distributors, regulators, investors and the press. It also replaces the survey in our carbon maths with a measured grid share, so the credits get more accurate as the network grows.

4 Going global

ROUTE	WHAT IT MEANS
Sell the proof	Metered home-solar verification as a service, priced per meter per month, for installers, pay-as-you-go solar firms and lenders in any emerging market.
Government buyers	Credits authorised under Paris Agreement Article 6 sell to countries that buy them for their own targets, usually above the voluntary price.
Pre-sold credits	A company pays upfront for an estate's future credits. That money funds the families' switch, with a branded impact dashboard.
Bigger generators	Telecom towers, clinics and factories across Africa run on diesel. More credits per site, same engine.
Diaspora	Nigerians abroad fund their parents' solar through Access and see the proof.
Access's footprint	The same deployment in each African country where Access operates, with local installers.

For Wednesday: dust alert built, message mocked up, trade-in and grid map pitched.

Sources on page 11.

Risks, and what we do about them

Every risk below is one a carbon judge or a credit officer would raise. Each has an answer we can show, not just say.

RISK	WHAT WE DO
Would they have gone solar anyway?	We grade homes still on generators and fund new switches through trade-in and loans. The pilot includes the barrier analysis the method asks for in Nigeria.[6]
Who pays to scrap the generator?	Its scrap value becomes the loan deposit; pre-sold credits fund larger estates.
Did they really use a generator?	Fuel receipts or history, nameplate photo, and the method's cap on creditable energy.[6]
They buy another generator	Signed contract, the 10% backup limit checked from inverter data, and the method's leakage penalty.
Inverter data is faked	Nine checks, a trust score, the hash-chained ledger, and an auditor's sample.
Emission factors are placeholders	1.59 and 0.40 t/MWh and the 5% adjustment are swapped for the method's annex values before any real filing.[8,10]
Counted twice	One serial per tonne, registered nationally; authorisation when sold to buyers who need it.[4,12]
Credit prices fall	The family's payout moves with price; the loan rests on metered savings, not on price.
No escrow in the sandbox	A holding wallet and our ledger for now; production escrow is in our ask.[9]
Why not tokenise credits?	Hash-chaining gives tamper evidence without a second tradable asset.
